September 1979

Foreword

This report presents population projections for Alberta Census Divisions by five year age groups and sex through to 1991. These projections were prepared by the Alberta Bureau of Statistics in co-operation with a Committee comprised of representatives from several Alberta Government departments and agencies. Committee members provided valuable suggestions and guidance in formulating assumptions and developing these projections. It is possible that while the projections reflect a consensus within the Committee, they may not correspond entirely with the policy and expectations of any one participating agency.

The assistance and co-operation of the departments and agencies listed below in making available personnel to contribute to the project through participation in the Committee are gratefully acknowledged:

Alberta Advanced Education and Manpower;
Alberta Economic Development;
Alberta Education;
Alberta Environment;
Alberta Hospitals and Medical Care;
Alberta Municipal Affairs;
Alberta Social Services and Community Health;
Energy Resources Conservation Board.

Census Division Population Projections

I. General Comments

Projection of a census division (CD) population is relatively more difficult than for a province due to the lack of satisfactory data. Population figures at the CD level are available by age and sex for census years only. Intercensal estimates of total population for CDs are available only since 1967. Vital statistics are available for total deaths by age and sex, and total births by age of mothers. No one satisfactory source of intraprovincial migration exists. One possibility explored was a system developed for Statistics Canada to estimate population flow between census divisions or counties, using tax files. Results obtained were not encouraging, errors of estimation being too large. The entire system is being further developed.

Another potential source for migration data is the health insurance registration record. Alberta Medical Care maintains a record of all persons covered under the Alberta Health Care Insurance Plan (AHCIP). Paying a substantial portion of personal costs for medical services provides an incentive to persons moving into the province to register with the AHCIP. On the other hand, no such incentive exists for a person leaving the province to apply for cancellation of his registration. Hence, the record of inflows of population is much more complete than for the outflows. Movement of people between census divisions is less likely to be on the AHCIP record as the insurance benefits to the registrants are not affected by their change of residence within the province. The AHCIP record can only trace such movements when either informed by the registrants of their change of address or from medical bills should the registrants happen to require medical services. The AHCIP record therefore does not provide sufficient basis for estimating inter-CD migration.

Family Allowance transfer of accounts records are being used in estimating interprovincial migration. A system to utilize this source in estimating small area migration is under development by the Systems and Computing Division of Health and Welfare Canada. This system will provide information on the movement of families (receiving family allowance) between any given areas within the province. Estimates of migration by census divisions may be possible by using this information provided some satisfactory method is developed. Currently no satisfactory methods are available which can be used to estimate migration at the CD level using one of the three above mentioned data bases. Total flows are difficult enough to obtain, but those by age and sex are extremely difficult. The intraprovincial migration components are critical for CD projections where the loci of economic activities are shifting from metropolitan areas to the other regional cities and towns.

In the absence of data on migration a trend analysis as well as the direct projection of migration is not possible. In order to project migration an indirect approach has been adopted. A detailed discussion of the migration methodology is given in Section IV.

Two sets of projections have been produced and are referred to as series 4 and series 5 to correspond to the designation of the provincial population projection series. (These two series were selected for publication based on an examination of all series by the Population Projections Committee.) In each case the sum of the census divisions population matches the corresponding provincial population total.

Users should note that these projections are not forecasts. These projections indicate possible distributions of future population and are based on trend analysis of total growth, components of natural increase and proportional distribution of Alberta population into census divisions and the present economic activities within each CD. Should a major change in factors influencing population growth in any CD occur the results of these projections could differ largely from the actual for that CD.

A cohort component approach was used in producing the census divisions population projections by age and sex. The word "cohort" indicates that computation is done by age, retaining the identity of each age group as it is carried forward through time.[1] "Component" refers to the inter-action of births, deaths and migration as population changes. To be more explicit:

$$P^1 = P + B - D + NM$$

where P is the population at the beginning of the period, P^1 is the population at the end of the period, B and D are births and deaths and NM is the net total migration.

For census division population projections each of the above components has been projected separately. The projection approach for each component is discussed in the following sections.

II. Mortality

Mortality rates in Alberta vary from one census division to another. For this reason survival probabilities were calculated separately for each census division as inputs to the census division projections. Mortality data at the CD level are of relatively lower quality than at the provincial level. Population estimates for intercensal years are available only since 1967, thus the scope for studying historical trends prior to 1967 was limited. However, this study has been based on an examination of past trends since 1966. In the following paragraphs a brief discussion on the mortality pattern, underlying assumptions and survival probabilities is provided.

Mortality rates at the provincial level in Alberta seem almost to have stabilized. In the case of census divisions the situation is a little different. Some divisions have shown a slow decline while others demonstrate a small increase. Varying levels of mortality from census division to census division may be due to the age composition of the CD population as well as socio-economic and demographic factors. In view of data limitations it was not possible to identify the reasons for differences in the mortality level of census divisions.

---

1 Technical paper 39, U.S. Department of Commerce, Bureau of Census.

Table 1 shows that in 1966 mortality rates for CD 10, at 10.43 deaths per thousand population, remained highest in the province. It was followed by CD 1 and CD 7 at 9.41 and 8.43 deaths per thousand population, respectively. In contrast, the death rate for CD 14, at 4.9 deaths per thousand, was the lowest in the province. The mortality rates for divisions 1, 2, 6, 8, 10, 12, and 15 have declined over the interval from 1966 to 1976. The rate of decline has been small. Similarly, in divisions 3, 4, 5, 7, 9, 11, 13 and 14 the increase in the death rate over the ten years 1966 to 1976 has been very small.

Infant Mortality: Infant mortality refers to deaths of children less than one year old. The infant mortality rate is expressed as the number of deaths per thousand live births. Reduction in the infant mortality rate is indicative of progress in controlling both the endogenous and exogenous causes of deaths. Table 2 shows the trend in infant mortality for Alberta census divisions for the period between 1968 and 1976. Infant mortality has declined in fourteen out of fifteen divisions. In Division 2 the infant mortality rate has increased from 11.6 to 15.9 deaths per thousand live births.

Child Mortality: This refers to deaths of persons one to fourteen years old. The reference period for this analysis is 1968 to 1976. Table 3 summarizes the child mortality pattern of Alberta census divisions. In some divisions the rates have declined, while in others they have increased. Those divisions where substantial reduction has occurred are 2, 4, 5, 6, 11, 13, 14 and 15. Divisons 1, 3, 7, 8, 9, 10 and 12 have shown increases in their levels between 1966 and 1976. The reason for such increases is not known. To arrive at a reasonable conclusion as to the future trend in child mortality a more detailed analysis is needed which is beyond the scope of this paper.

Source: Prepared by Alberta Bureau of Statistics using unpublished data on deaths for Census Divisions from Statistics Canada and Bureau of Vital Statistics.

Early and Middle Adult Mortality: This refers to deaths occurring between 15 and 54 years of age. In some census divisions the mortality rates of the adult population have declined during the period 1968 to 1976. Those divisions where the rates have declined are 2, 4, 5, 6, 9, 10, 11, 13, and 14. In contrast, the rates have increased in divisions 1, 3, 7, 8, 12 and 14.

3. Population aged 55+

Source: Alberta Bureau of Statistics

Late Adult Mortality: Some signifiant changes have occurred to the late adult mortality in some of the divisions. Divisions 3, 5, 8 and 14 have shown high increases in the rate of late adult mortality, whereas high reductions have occurred in divisions 1, 2, 4, 7 and 10. In the remaining divisions marginal changes have occurred to the late adult mortality. Table 3 shows the late adult mortality for the years 1968 and 1976.

Assumptions:

The following assumptions have been made regarding mortalitv:

1. Mortality patterns of Alberta census divisions will not change significantly over the projection period, from that shown by the average of 1969 - 1976.

2. A small decline in infant mortality is expected to occur in some of the census divisions, but it will not be so significant as to affect the age distribution of the population during the projection period.

3. Changes in the mortality level of Alberta census divisions will not be large. It is assumed that any changes in the mortality levels of census divisions will not affect the projection results adversely.

Survival Rates:

The next step involved in the projection of number of deaths is the calculation of survival rates. Abridged life tables were calculated for individual census divisons for each sex. For detailed information in the calculation of survival ratios and the life table please see "Life Tables and Survival Ratios for Census Divisions of Alberta".[1]

---

1 Copies of the abridged life tables are available from the Alberta Bureau of Statistics.

III. Fertility

Population increases through births and in-migration and decreases through deaths and out-migration. Fertility is, therefore, one of the important parameters of population change. It is a function of a number of factors such as population composition, ethnic and religious influences, participation of women in the labour force, level of schooling, age at marriage, etc. In a study of fertility an account of the influence of these factors becomes necessary. At the sub-provincial level, information related to these variables is not available, the only available statistics being the number of births by age of mother and the total population estimates for intercensal years. Population by age and sex is available for census years only. From the available statistics total fertility rates for each division were generated for census years 1966, 1971 and 1976 and for intercensal years between 1966 and 1971. Historical trends in fertility rates were examined and assumptions concerning future patterns were derived.

Trend:

Fertility rates in census divisions of Alberta have declined considerably during the last ten years since 1966. There exists considerable variation between census divisions in their rates and in the rate of fertility decline.

The total fertility rates vary from a low of 1.71 births per woman (aged 15-49) in CD 6 (1976) to a high of 3.33 in CD 14 (1976) as compared to a low of 2.76 in CD 1 (1966) and a high of 4.07 in CD 15 (1966). The average annual rate of decline varies from a high of 4.6 percent for CD 10 to a low of 1.1 percent for CD 14. It will be noticed in Table 4 that the total fertility rates for divisions 1, 8, 9, 10, 11 and 13 are lower than that for the province in 1976, while in the remaining divisions they are higher than the provincial rate.

Note: Rates are births per 1,000 women aged 15-49 during a calendar year.

Sources: 1) Total fertility rates for Census Divisions were prepared by the Alberta Bureau of Statistics.

2) Provincial total fertility rates are from "Vital Statistics Annual, Volume 1, Births" Statistics Canada Catalogue No. 84-204.

The past patterns of change in the fertility rates for Alberta census divisions indicate a general decline for all divisions. Further decline in the rates for most of the divisions is very likely to occur where the fertility level is much above the provincial level.

Assumptions:

In the light of the above examination of the fertility patterns, the following assumptions have been made:

I. Fertility rates for Alberta census divisions will continue to decline until they reach replacement level.

II. Census divisions with rates lower than replacement level will level off at their current rate.

III. In-migration population will be subjected to the same fertility level as that of the census division base population.

Projection Methodology:

For the projection of total fertility rates at the CD level, a linear approach was adopted. Historical data on total fertility rates for the period 1966-76 were examined and ratios of census divisions to Alberta total fetility rates were obtained and linearly extrapolated. In order to get the projected total fertility rates, these ratios were multiplied by the projected total fertility rates for Alberta to obtain the fertility projections for each census division for the years 1977-1991.

The total fertility rates used in this study are from "Population Projections, Alberta 1977-2006".

IV. Migration

Migration may be defined as the change in residence of a person from one geographically defined area to another. Migration affecting a census division may occur from movement of people from other census divisions within the province, or from outside the province but within Canada or from outside the national boundaries. It is difficult, if not impossible, to maintain a record of such movement. Data on this movement of population at the census division level are scarce. Selection of a methodology posed some problems. One serious limitation is that migration estimates at the census division level are not available. Thus a study of migration trends is very difficult. The method adopted to develop migration assumptions is a residual approach which determines migration to be the difference of total growth and natural increase in the population. The methodology in brief is discussed below.

Methodology:

Ratios of CD to provincial population were calculated for census years 1951 to 1976. Changes in these ratios for each census division were examined and extrapolated mathematically. Projected ratios were then adjusted in the light of information on ongoing and proposed capital investment in each of these divisions. This is done because economic forces have demonstrated their significant influence on population growth in Alberta, in the most recent years. In view of the very dynamic nature of the Alberta economy the Projection Committee suggested the projected trends in ratios be subjected to the influence of anticipated economic activities in Alberta census divisions. This procedure is similar to one considered by the University of Nebraska in preparing "Nebraska Population Projections: State, County, Region and Towns: 1975-2020".[1]

---

1 Nebraska Economic and Business Report No. 6. Omaha: Bureau of Business Research and Center for Applied Urban Research, 1973.

Projected ratios were then aggregated to equal one. Any difference from unity was redistributed to all the divisions so that the total is unity. After adjustment these ratios were used to distribute the projected provincial population into census divisions for each year. Projected populations were then aggregated to match the provincial total for respective years.

In the second step the 1976 census population by single years of age for each division was projected by the cohort-component approach assuming no migration. Projected total fertility rates, and constant survival probabilities were used in projecting the CD population. The projected closed population total was then subtracted from that obtained by the ratio method. Differences obtained for the first year were considered a proxy to the net migration in that year. First year difference when subtracted from the second year difference gave the assumed net migration for the second year. This procedure was followed to derive migration estimates for successive years.

More explicitly, if P_{ij} is the total projected population and $P1_{ij}$ is the projected population with no migration

for division i, i = 1, ...15

and year j, j = 1, ...n

then the net migration estimate will be

$$M_{i1} = (P_{i1} - P1_{i1})$$

$$M_{i2} = (P_{i2} - P1_{i2}) - (P_{i1} - P1_{i1})$$

$$\cdot$$

$$\cdot$$

$$M_{ij} = (P_{ij} - P1_{ij}) - (P_{i(j-1)} - P1_{i(j-1)})$$

$$\cdot$$

$$\cdot$$

$$M_{in} = (P_{in} - P1_{in}) - (P_{i(n-1)} - P1_{1(n-1)}).$$

Migration estimates derived from this approach need adjusting to remove the natural increase in the migrant population. It is small in the case of small divisions and can be ignored, however, it could be quite significant in those CDs with larger populations. This adjustment was made in the following manner.

The rate of natural increase for each individual division was calculated and applied to previous years migrant population. Estimated natural increase in the migrant population was then subtracted from the migration estimates. More explicitly, if the rate of natural increase in the population is $N_{i(j-1)}$ for the ith division and the j-1th year, the amount of overestimation will be:

$$M_{i(j-1)} \times N_{i(j-1)}.$$

The corrected migration estimates, therefore, will be:

$$M_{ij} - (M_{i(j-1)} \times N_{i(j-1)}).$$

Migrants' Age Distribution: This distribution is an important requirement in producing projections by age-sex. At the census division level such data are available only for census years and for selected age groups. This limitation has created considerable problems. Another source of data is the Alberta Health Care Registration records which provide migration estimates by census divisions. Overall examination of the two sources lead to the conclusion that Health Care provides a more realistic estimate of in-migrants by age and sex than does the census. By assuming that the age structure of in-migrants is representative of that of all migrants, Health Care records have been used to obtain the migrant's age distribution.

Conclusion

The methodology used in deriving the Census Division projections has been outlined in the previous sections. In sections V and VI the two sets of projections are presented by five year age groups by sex. These two sets are based on Series 4 and Series 5 of the provincial population projections (Population Projections, Alberta, 1977-2006. Alberta Bureau of Statistics, February, 1979).
